Natural Language Processing & Word Embeddings

Quiz, 10 questions

1 point	1.	Suppose you learn a word embedding for a vocabulary embedding vectors should be 10000 dimensional, so as variation and meaning in those words.	
		True	
		False	
		€9	
1 point	2.	What is t-SNE? A linear transformation that allows us to solve a	analogies on word vectors
		A non-linear dimensionality reduction techniqu	e
		A supervised learning algorithm for learning wo	ord embeddings
		An open-source sequence modeling library	
1 point	3.		which has been trained on a huge
		corpus of text. You then use this word embedding to trace recognizing if someone is happy from a short snippet of the company	ain an RNN for a language task of fext, using a small training set.
		recognizing if someone is happy from a short snippet o	ain an RNN for a language task of
		recognizing if someone is happy from a short snippet o	ain an RNN for a language task of fext, using a small training set. y (happy?)
		x (input text) I'm feeling wonderful today!	ain an RNN for a language task of fext, using a small training set. y (happy?)
		x (input text) I'm feeling wonderful today! I'm bummed my cat is ill.	y (happy?) 1 0 1 r small training set, your RNN
		x (input text) I'm feeling wonderful today! I'm bummed my cat is ill. Really enjoying this!	y (happy?) 1 0 1 or small training set, your RNN

1 point	4.	all that apply)
		$e_{boy} - e_{girt} \approx e_{sister} - e_{brother}$
		$ e_{boy} - e_{brother} \approx e_{sister} - e_{girl} $
1 point	5.	Let E be an embedding matrix, and let o_{1234} be a one-hot vector corresponding to word 1234. Then to get the embedding of word 1234, why don't we call $E*o_{1234}$ in Python?
		It is computationally wasteful.
		$\bigcirc \text{The correct formula is } E^T * o_{1234}.$
		This doesn't handle unknown words (<unk>).</unk>
		None of the above: calling the Python snippet as described above is fine.
1 point	6.	None of the above: calling the Python snippet as described above is fine. When learning word embeddings, we create an artificial task of estimating $P(target \mid context).$ It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings. True
	6.	When learning word embeddings, we create an artificial task of estimating $P(target \mid context)$. It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings.
	6.	When learning word embeddings, we create an artificial task of estimating $P(target \mid context)$. It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings.
	 7. 	When learning word embeddings, we create an artificial task of estimating $P(target \mid context)$. It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings.
point 1		When learning word embeddings, we create an artificial task of estimating $P(target \mid context)$. It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings. True False
point 1		When learning word embeddings, we create an artificial task of estimating $P(target \mid context)$. It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings. True False In the word2vec algorithm, you estimate $P(t \mid c)$, where t is the target word and c is a context word. How are t and c chosen from the training set? Pick the best answer.
point 1		When learning word embeddings, we create an artificial task of estimating $P(target \mid context)$. It is okay if we do poorly on this artificial prediction task; the more important by-product of this task is that we learn a useful set of word embeddings. True False In the word2vec algorithm, you estimate $P(t \mid c)$, where t is the target word and c is a context word. How are t and t chosen from the training set? Pick the best answer. t is the one word that comes immediately before t .

1 point 8. Suppose you have a 10000 word vocabulary, and are learning 500-dimensional word embeddings. The word2vec model uses the following softmax function:

$$P(t\mid c) = \frac{e^{\theta_t^T e_c}}{\sum_{t'=1}^{10000} e^{\theta_t^T e_c}}$$

Which of these statements are correct? Check all that apply.

 θ_t and e_c are both 500 dimensional vectors.

 θ_t and e_c are both 10000 dimensional vectors.

 θ_t and e_c are both trained with an optimization algorithm such as Adam or gradient descent.

After training, we should expect θ_t to be very close to e_c when t and c are the same word.

1 point **9.** Suppose you have a 10000 word vocabulary, and are learning 500-dimensional word embeddings. The GloVe model minimizes this objective:

$$\min \sum_{i=1}^{10,000} \sum_{j=1}^{10,000} f(X_{ij}) (\theta_i^T e_j + b_i + b_j' - log X_{ij})^2$$

Which of these statements are correct? Check all that apply.

 θ_i and e_j should be initialized to 0 at the beginning of training.

lacksquare $heta_i$ and e_j should be initialized randomly at the beginning of training.

 X_{ij} is the number of times word i appears in the context of word j.

The weighting function f(.) must satisfy f(0) = 0.

1 point 10. You have trained word embeddings using a text dataset of m_1 words. You are considering using these word embeddings for a language task, for which you have a separate labeled dataset of m_2 words. Keeping in mind that using word embeddings is a form of transfer learning, under which of these circumstance would you expect the word embeddings to be helpful?

 $\bigcap m_1 << m_2$
